

CSCI 270 - Spring 2023 - HW 4

Due: February 8, 2023

Graded Problems

1. [10 points] Design a data structure that has the following properties (assume n elements in the data structure, and that the data structure properties need to be preserved at the end of each operation):
 - Find median takes $\mathcal{O}(1)$ time
 - Insert takes $\mathcal{O}(\log n)$ time

Do the following:

- (a) Describe how your data structure will work.
 - (b) Give algorithms that implement the Find-Median() and Insert() functions.
2. [10 points] Let us say that a graph $G = (V, E)$ is a near tree if it is connected and has most $n + k$ edges, where $n = |V|$ and k is a **constant**. Give an algorithm with running time $\mathcal{O}(n)$ that takes a near tree G with costs on its edges, and returns a minimum spanning tree of G . You may assume that all edge costs are distinct.
 3. [14 points] A new startup FastRoute wants to route information along a path in a communication network, represented as a graph. Each vertex and each edge represent a router and a wire between routers respectively. The wires are weighted by the maximum bandwidth they can support. FastRoute comes to you and asks you to develop an algorithm to find the path with maximum bandwidth from any source s to any destination t . As you would expect, the bandwidth of a path is the minimum of the bandwidths of the edges on that path; the minimum edge is the bottleneck. Explain how to modify Dijkstra's algorithm to do this.
 4. [20 points] Given a connected graph $G = (V, E)$ with positive edge weights. In V , s and t are two nodes for shortest path computation, prove or disprove with explanations:

- (a) If all edge weights are unique, then there is a single shortest path between any two nodes in V .
 - (b) If each edge's weight is increased by k , the shortest path cost between s and t will increase by a multiple of k .
 - (c) If the weight of some edge e decreases by k , then the shortest path cost between s and t will decrease by at most k .
 - (d) If each edge's weight is replaced by its square, i.e., w to w^2 , then the shortest path between s and t will be the same as before but with different costs.
5. [16 points] Consider a directed, weighted graph G where all edge weights are positive. You have one Star, which allows you to change the weight of any one edge to zero. In other words, you may change the weight of any one edge to zero. Propose an efficient method based on Dijkstra's algorithm to find a lowest-cost path from node s to node t , given that you may set one edge weight to zero.

Ungraded Problems

6. Consider a directed, weighted graph G where all edge weights are positive. You have one Star, which allows you to change the weight of any one edge to zero. In other words, you may change the weight of any one edge to zero. Propose an efficient method based on Dijkstra's algorithm to find a lowest-cost path from node s to node t , given that you may set one edge weight to zero.
